Lumpy Investment, Fluctuations in Volatility and Monetary Policy

Min Fang
University of Florida

April 21, 2023
@ I85 Macro Workshop

Motivation

- Known: Monetary policy has significant effects on investment

Motivation

- Known: Monetary policy has significant effects on investment
- Known: ***Elevated volatility*** of firm-level TFP leads to less investment

  (all firms experience an increase in the variance of their productivity shocks)

Motivation

- Known: Monetary policy has significant effects on investment
- Known: ***Elevated volatility*** of firm-level TFP leads to less investment

  (all firms experience an increase in the variance of their productivity shocks)
- Unknown: What is the role of volatility in monetary transmission on investment?

Motivation

- Known: Monetary policy has significant effects on investment
- Known: ***Elevated volatility*** of firm-level TFP leads to less investment

  (all firms experience an increase in the variance of their productivity shocks)
- Unknown: What is the role of volatility in monetary transmission on investment?
  1. Does effect of monetary policy depend on the level of volatility?

Motivation

- Known: Monetary policy has significant effects on investment
- Known: ***Elevated volatility*** of firm-level TFP leads to less investment

  (all firms experience an increase in the variance of their productivity shocks)

- Unknown: What is the role of volatility in monetary transmission on investment?

  1. Does effect of monetary policy depend on the level of volatility?
  2. Why does it matter?

Motivation

- Known: Monetary policy has significant effects on investment
- Known: ***Elevated volatility*** of firm-level TFP leads to less investment

  (all firms experience an increase in the variance of their productivity shocks)
- Unknown: What is the role of volatility in monetary transmission on investment?

  1. Does effect of monetary policy depend on the level of volatility?
  2. Why does it matter?

     [One of the reasons]: It affects the amount of monetary policy stimulus required in high volatility times like now or in the Great Recession.

The detailed questions

Q1: What are the estimates of $\boxed{\frac{dI}{d\epsilon^m}(\sigma)}$ for different σ in the data?

In words: How does an increase in volatility of firm-level TFP affect the impact of monetary policy on aggregate investment?

The detailed questions

Q1: What are the estimates of $\boxed{\frac{dI}{d\epsilon^m}(\sigma)}$ for different σ in the data?

In words: How does an increase in volatility of firm-level TFP affect the impact of monetary policy on aggregate investment?

Q2: Could micro-founded macro models explain the estimates? And how?

In words: What key micro-foundations of the model could replicate the observations in the data?

Answers in this paper

Q1: What are the estimates of $\boxed{\frac{dI}{d\epsilon^m}(\sigma)}$ for different σ in the data?

- Empirical: Monetary stimulus is less effective in times of high volatility

Answers in this paper

Q1: What are the estimates of $\boxed{\frac{dI}{d\epsilon^m}(\sigma)}$ for different σ in the data?

  (2) Sensitivity of Investment: Responsiveness to interest rate and volatility

Answers in this paper

Q1: What are the estimates of $\boxed{\frac{dI}{d\epsilon^m}(\sigma)}$ for different σ in the data?

- Empirical: Monetary stimulus is less effective in times of high volatility

Q2: Could micro-founded macro models explain the estimates? And how?

- Theory: Develop a NK model w/ heterogeneous firms + volatility shock
- Model consistent with both micro & macro evidence of investment:

  (1) Lumpy Investment: Inaction/Spikes (E.M.) of firm-level investment

  (2) Sensitivity of Investment: Responsiveness to interest rate and volatility
- Aggregate transmission depends on the level of volatility:

  Monetary policy is less effective when volatility is elevated

Key mechanism in the model

- Aggregate investment = extensive margin + intensive margin:

$$I = \sum_{j \in EM} i_j + \sum_{j \in IM} i_j$$

- **① Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d \sum_{j \in EM} i_j}{d \epsilon_t^m} (\sigma_t) \downarrow \text{ , when } \sigma_t \uparrow$$

- **② Reasonable sensitivity of investment to interest rate and volatility**

$$\text{Both data consistent } \frac{d \sum_{j \in EM} i_j}{dr} \quad \& \quad \frac{d \sum_{j \in EM} i_j}{d\sigma}$$

Key mechanism in the model

- The inv. channel of monetary policy works through both margins:

$$\frac{dI}{d\epsilon_t^m} = \frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m} + \frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}$$

- 1 **Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow \;, \text{ when } \; \sigma_t\uparrow$$

- 2 **Reasonable sensitivity of investment to interest rate and volatility**

$$\text{Both data consistent } \frac{d\sum_{j\in EM} i_j}{dr} \;\&\; \frac{d\sum_{j\in EM} i_j}{d\sigma}$$

Key mechanism in the model

- The inv. channel of monetary policy works through both margins:

$$\frac{dI}{d\epsilon_t^m} = \frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m} + \frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}$$

- **1 Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow \text{ , when } \sigma_t\uparrow$$

- **2 Reasonable sensitivity of investment to interest rate and volatility**

$$\text{Both data consistent } \frac{d\sum_{j\in EM} i_j}{dr} \quad \& \quad \frac{d\sum_{j\in EM} i_j}{d\sigma}$$

Key mechanism in the model

- Monetary policy is less effective stimulating aggregate investment:

$$\underbrace{\frac{dI}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} = \underbrace{\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} + \underbrace{\frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\approxeq} \text{, when } \sigma_t \uparrow$$

- **1 Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow \text{, when } \sigma_t \uparrow$$

- **2 Reasonable sensitivity of investment to interest rate and volatility**

$$\text{Both data consistent } \frac{d\sum_{j\in EM} i_j}{dr} \quad \& \quad \frac{d\sum_{j\in EM} i_j}{d\sigma}$$

Key mechanism in the model

- Monetary policy is less effective stimulating aggregate investment:

$$\underbrace{\frac{dI}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} = \underbrace{\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} + \underbrace{\frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\approx}, \text{ when } \sigma_t \uparrow$$

- 1 **Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow, \text{ when } \sigma_t \uparrow$$

- Could we take the extensive margin mechanism 1 as granted?
  - Is any extensive margin (lumpy inv.) model sufficient to generate this result?

Key mechanism in the model

- Monetary policy is less effective stimulating aggregate investment:

$$\underbrace{\frac{dI}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} = \underbrace{\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} + \underbrace{\frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\approx}, \text{ when } \sigma_t \uparrow$$

- 1 **Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow, \text{ when } \sigma_t \uparrow$$

- No. We still need two dynamic properties from the micro-foundation:
  - Data consistent interest rate sensitivity of $I \Rightarrow$ a reasonable $\frac{d\sum_{j\in EM} i_j}{dr}$
  - Data consistent volatility sensitivity of $I \Rightarrow$ a reasonable $\frac{d\sum_{j\in EM} i_j}{d\sigma}$

Key mechanism in the model

- Monetary policy is less effective stimulating aggregate investment:

$$\underbrace{\frac{dI}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} = \underbrace{\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} + \underbrace{\frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\approx}\text{ , when } \sigma_t \uparrow$$

- **1 Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)\downarrow\text{ , when } \sigma_t \uparrow$$

- **2 Reasonable sensitivity of investment to interest rate and volatility**

Both data consistent $\frac{d\sum_{j\in EM} i_j}{dr}$ & $\frac{d\sum_{j\in EM} i_j}{d\sigma}$

Literature review

1. **Volatility/State-dependent Effects of Monetary Policy**
   Vavra (2013), Koby&Wolf (2019), Baley&Blanco (2019), Li (2020), McKay&Wieland (2020), Castelnuovo&Pellegrino (2018), Eickmeier et al. (2016);
   I show that the inv. channel of monetary policy is also volatility-dependent.
2. **New Keynesian Models with Capital Accumulation**
   Christiano et al. (2005), Smets&Wouters (2003,2007), Reiter et al. (2013), Ottonello&Winberry (2018), Jeenas (2018);
   I show that the lumpy inv. could co-exist with reasonable inv. IRFs. w.r.t. MP.
3. **Volatility in RBC and/or for Stimulus Policy**
   Abel et al. (1996), Dixit et al. (1994), Bloom (2009), Bloom et al. (2018), Bachmann&Bayer (2013), Gilchrist et al. (2014), Arellano,Bai,&Kehoe (2019);
   I show that second-moment shocks reduce the effects of first-moment policy.
4. **Aggregate Implications of Lumpy Investment**
   Caballero et al. (1995), Caballero&Engel (1999), Thomas (2002), Khan&Thomas (2008), Bachmann et al. (2013), House (2014), Winberry (2018b), Koby&Wolf (2019), Baley&Blanco (2020);
   I show that lumpy investment matters for monetary policy as well.

Roadmap

Q1: What are the estimates of $\frac{dI}{d\epsilon^m}(\sigma)$ for different σ in the data?

0. Local projection of investment responses to identified monetary shocks

Q2: Could micro-founded macro models explain the estimates? And how?

1. A heterogeneous firm New Keynesian model with lumpy investment
2. Volatility shock and the solution method
3. Parameterization and identification of lumpy investment
4. Volatility-dependent effectiveness of monetary policy
5. Inspecting the mechanism in the model

[Empirical Motivation]
Q1: What is $\frac{dI}{d\epsilon^m}(\sigma)$ for different σ in the data?

Data ▸ Details

Quarterly National Income and Product Account + Monetary Shocks + Volatility

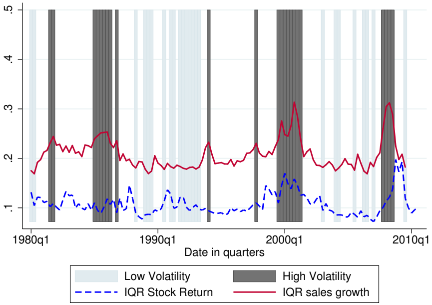
- Investment Indicator: Real non-residential private fixed investment
- Monetary Shocks: High-frequency-identified from Gertler-Karadi-2015
- Volatility Indicator: Interquantile Range (IQR) of sales growth

Data ▸ Details

Quarterly National Income and Product Account + Monetary Shocks + Volatility

- Investment Indicator: Real non-residential private fixed investment
- Monetary Shocks: High-frequency-identified from Gertler-Karadi-2015
- Volatility Indicator: Interquantile Range (IQR) of sales growth

Figure: Top20% vs Bottom 20%: 0.18 vs 0.26



Empirical strategy

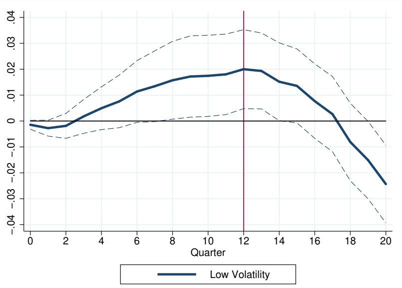
Baseline Local Projection Specification following Jorda (2005)

$$\Delta_h I_{t+h} = \alpha_h + \boldsymbol{\gamma_{j,h}} \epsilon_t^m \times \mathbf{1}_{\sigma_t \in J^\sigma} + \sum_{l=0}^{L} \Gamma'_{h,t-l} Z_{t-l} + \epsilon_{h,t} \tag{1}$$

- $\sigma_t \in J^\sigma \equiv \{h, m, l\}$ indicates which group level of volatility at time t belongs to
- $\sigma_t = IQR_{sg,t}$ is the sales growth interquantile range of 25yr+ Compustat firms
- ϵ_t^m is sign-flipped and standardized monetary policy shock (/-25bps)
- Z_{t-l}: conditional on volatility group, consumer price index (CPI), output gap, and consumption up to four quarters $L = 4$; α_h: h-period ahead fixed effect
- Coefficient $\boldsymbol{\gamma_{j,h}}$ measures slope of investment semi-elasticity w.r.t. volatility

Inv. response to monetary stimulus with low volatility

- Impulse Response to monetary policy shock:

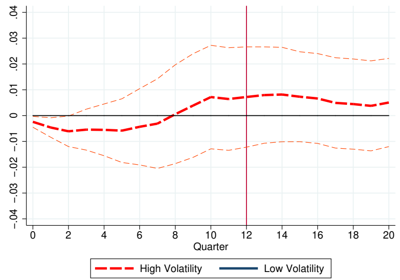


- Effectiveness of monetary policy:

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data	2.0%	0.18				

Inv. response to monetary stimulus with high volatility

- Impulse Response to monetary policy shock:

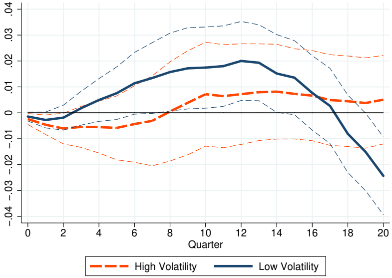


- Effectiveness of monetary policy:

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data			0.75%	0.26		

High volatility lowers inv. responses to monetary stimulus

- Impulse Response to monetary policy shock:



- Reduction in the effectiveness of monetary policy: **62%**

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data	2.0%	0.18	0.75%	0.26	**62%**	44%

Robustness of main result & additional facts

- Robustness Checks:

Choices	LP Form	MP shock ϵ_t^m	Volatility σ_t	Investment	Periods
1	Grouped	GK-HFI	IQR sales growth	RGFCF	80-10
2	Interacted	RIR	IQR stock return	RGPI	85-10
3				RPFI	85-07
4				RPFI-NR	80-07
5				RPFI-NR-EQMT	60-10
6				RPFI-NR-Struct	60-07
7				RPFI-NR-IP	60-18

  - Interacted: replacing $\gamma_{j,h}\epsilon_t^m \times \mathbf{1}_{\sigma_t \in J^\sigma}$ with $(\beta_h + \gamma_h \sigma_t) \times \epsilon_t^m$ Results
  - Almost all hold in all $2 \times 2 \times 2 \times 7 \times 7 - 2 \times 2 \times 7 \times 3 = 308$ alternatives

- Additional Facts: Firm-level Regressions
  - Firm-level regressions using Compustat Quarterly
  - Tobit and Probit Local Projections to inspect mechanism

[Quantitative Theory]

Q2: Could micro-founded macro models explain the estimates? And how?

Roadmap of the Quantitative Theory

1. **A heterogeneous firm New Keynesian model with lumpy investment**
2. Volatility shock and the solution method
3. Parameterization and identification of lumpy investment
4. Volatility-dependent effectiveness of monetary policy
5. Inspecting the mechanism in the model

Model overview

Heterogeneous Production Firms:

- Produce and invest subject to capital adj. costs
- Face idiosyncratic productivity shocks

A New Keynesian Block

- Retailers differentiate production firms' output + Rotemberg sticky price
- Monetary authority follows Taylor Rule

A Family of Representative Households

- Owns firms + choose consumption, hours of working, and saving.

Production firms

Enter period with state variables (z_{jt}, k_{jt})

1. Production:

$$y_{jt} = z_{jt} k_{jt}^{\alpha} n_{jt}^{\nu}, \quad \alpha + \nu < 1 \tag{2}$$

   - Sell at relative price p_t^w

2. Idiosyncratic TFP shock:

$$log(z_{jt}) = -\frac{{\sigma_z}^2}{2(1+\rho)} + \rho_z log(z_{jt-1}) + \sigma_z \epsilon_{jt} \tag{3}$$

Production Firms

Enter period with state variables (z_{jt}, k_{jt})

Cost of Investment:

$$c(i_j) = i_j + \frac{\phi_k}{2} \left| \frac{i_j}{k_j} \right|^2 k_j + \mathbf{1}_{(i_j<0)} \cdot S \cdot |i_j| + \mathbf{1}_{(i_j \notin [-ak, ak])} \cdot \xi_j \cdot w_t \tag{4}$$

$$\xi_j \sim U[0, \bar{\xi}]$$

1. Quadratic Adj. Costs ϕ_k:
   - Extremely costly to make huge changes in capital stock
2. Partial Irreversibility S: Disinvestment will cost S proportional loss in inv.
   - Caution of investment today because of potential disinvest costs tomorrow
3. Random Fixed Costs ξ_j: Randomly occurred cost paid in unit of labor
   - "Lucky" or "unlucky" draws determine inaction or action

Investment policy

Recursive Production Firms' Problem

- Optimal Investment Decisions

$$\text{Extensive Margin: } \xi_t^*(k_{jt}, z_{jt}; \Omega_t) = \frac{V^A(k_{jt}, z_{jt}; \Omega_t) - V^{NA}(k_{jt}, z_{jt}; \Omega_t)}{w_t} \tag{5}$$

$$\text{Intensive Margin: } k_{jt+1} = \begin{cases} (1-\delta)k_{jt} + i_{jt}^* & \xi_{jt} < \xi^*(k_{jt}, z_{jt}; \Omega_t) \\ (1-\delta)k_{jt} + i_{jt}^C & \textit{otherwise} \end{cases} \tag{6}$$

- Both irreversibility and fixed cost create inactions at the extensive margin:
  - Irreversibility governs $\xi_t^*(k_{jt}, z_{jt}; \Omega_t)$ sensitivity to volatility
  - Fixed Cost governs $\xi_t^*(k_{jt}, z_{jt}; \Omega_t)$ sensitivity to interest rate

Retailers and final good producer

- Monopolistically competitive retailers
  - Technology: $\tilde{y}_{jt} = y_{jt} \Rightarrow$ marginal cost $= p_t^w$
  - Subject to price adj. costs: $AC_p = \frac{\psi_p}{2}\left(\frac{p_{jt}}{p_{jt-1}} - 1\right)^2 P_t Y_t$
- Perfectly competitive final good producer
  - Technology: $Y_t = \left(\int \tilde{y}_{jt}^{\frac{\gamma-1}{\gamma}} dj\right)^{\frac{\gamma}{\gamma-1}} \Rightarrow P_t = \left(\int p_{jt}^{1-\gamma} dj\right)^{\frac{1}{1-\gamma}}$

Retailers and final good producer

- Monopolistically competitive retailers
  - Technology: $\tilde{y}_{jt} = y_{jt} \Rightarrow$ marginal cost $= p_t^w$
  - Subject to price adj. costs: $AC_p = \frac{\psi_p}{2}\left(\frac{p_{jt}}{p_{jt-1}} - 1\right)^2 P_t Y_t$
- Perfectly competitive final good producer
  - Technology: $Y_t = \left(\int \tilde{y}_{jt}^{\frac{\gamma-1}{\gamma}} dj\right)^{\frac{\gamma}{\gamma-1}} \Rightarrow P_t = \left(\int p_{jt}^{1-\gamma} dj\right)^{\frac{1}{1-\gamma}}$
- Implies the **New Keynesian Phillips curve**

$$log\Pi_t = \frac{\gamma - 1}{\psi_p} log\frac{p_t^w}{p^{w*}} + \beta E_t log\Pi_{t+1}$$

Monetary authority and household

- Monetary authority follows the **Taylor rule**

$$logR_t^n = log\frac{1}{\beta} + \phi_\Pi log\pi_t + \epsilon_t^m$$

Monetary authority and household

- Monetary authority follows the **Taylor rule**

$$logR_t^n = log\frac{1}{\beta} + \phi_\Pi log\pi_t + \epsilon_t^m$$

- A family of representative household with preferences

$$E_0 \sum_{t=0}^{\infty} \beta^t \left(\frac{C_t^{1-\eta}}{1-\eta} - \theta N_t \right)$$

  - Labor-leisure choice $\Rightarrow w_t = \theta C_t^\eta$
  - Consumption-saving choice $\Rightarrow \Lambda_{t,t+1} = \beta \left(\frac{C_t}{C_{t+1}} \right)^\eta$

Stationary Equilibrium

- An **equilibrium of this model satisfies**
  1. Production firms choose investment policies $k_t'(z,k)$ and $\xi_t^*(z,k)$
  2. Retailers and final good producers generate NK Phillips curve
  3. Monetary authority follows Taylor rule $logR_t^n = log\frac{1}{\beta} + \phi_\Pi log\pi_t + \epsilon_t^m$
  4. Households choose labor supply N_t and generate SDF $\Lambda_{t,t+1}$

Roadmap of the Quantitative Theory

1. A heterogeneous firm New Keynesian model with lumpy investment
2. **Volatility shock and the solution method**
3. Parameterization and identification of lumpy investment
4. Volatility-dependent effectiveness of monetary policy
5. Inspecting the mechanism in the model

Solve the stationary equilibrium

- Solve the stationary equilibrium (policy/distribution) with no aggregate risk
  - Non-stochastic simulation (Young, 2010) for value/policy functions
  - Stochastic simulation for parameterization sample
- Compute the stationary equilibrium moments
  - Steady state investment distribution moments
  - Use for identification of lumpy investment parameters

Solve the transitional equilibrium

- Volatility shock: a MIT shock (unexpected increase) to the variance σ_z timing

$$log(z_{jt}) = -\frac{{\sigma_z}^2}{2(1+\rho)} + \rho_z log(z_{jt-1}) + \sigma_z \epsilon_{jt}$$

Solve the transitional equilibrium

- Volatility shock: a MIT shock (unexpected increase) to the variance σ_z timing

$$log(z_{jt}) = -\frac{{\sigma_z}^2}{2(1+\rho)} + \rho_z log(z_{jt-1}) + \sigma_z \epsilon_{jt}$$

- Compute perfect foresight transition path following aggregate shocks
  - Case One: MP shock only; Case Two: MP shock + Vol. shock

Solve the transitional equilibrium

- Volatility shock: a MIT shock (unexpected increase) to the variance σ_z timing

$$log(z_{jt}) = -\frac{\sigma_z{}^2}{2(1+\rho)} + \rho_z log(z_{jt-1}) + \sigma_z \epsilon_{jt}$$

- Compute perfect foresight transition path following aggregate shocks
  - Case One: MP shock only; Case Two: MP shock + Vol. shock
  - I update all aggregate price paths all at once using ***excessive demand*** which is super fast (seconds for 200 periods even without parallel computing)
  - Captures all non-linear dynamics following a volatility shock (Global sol.)
  - Captures all non-linear dynamics of interactions between shocks which is the key that the results in this model is achieved

Roadmap of the Quantitative Theory

1. A heterogeneous firm New Keynesian model with lumpy investment
2. Volatility shock and the solution method
3. **Parameterization and identification of lumpy investment**
4. Volatility-dependent effectiveness of monetary policy
5. Inspecting the mechanism in the model

Fixed parameters

Parameter	Description	Value
Households		
β	Discount factor	0.99
η	Elasticity of intertemporal substitution	1
θ	Leisure preference	2
Production Firms		
α	Capital coefficient	0.25
ν	Labor coefficient	0.60
δ	Capital depreciation	0.026
ρ_z	Persistence of TFP shock	0.95
New Keynesian		
γ	Demand elasticity	10
ψ_p	Price adjustment cost	90
ϕ_π	Taylor rule coefficient	1.5

Parameters to be computed

- How large should the volatility be, respectively?

Parameter	Description	Value
Volatility Level		
σ_z^l	Volatility of TFP shock (normal time)	0.05
σ_z^h	Volatility of TFP shock (elevated)	0.13

- Moments to match

Moment	Data	Model
IQR sales growth IQR_{sg} (normal time)	0.18	0.18
IQR sales growth IQR_{sg} (elevated)	0.26	0.26

Details of the simulation

Parameters to be computed

- Recap of the Cost Function of Investment:

$$c(i_j) = i_j + \frac{\phi_k}{2} \left| \frac{i_j}{k_j} \right|^2 k_j + \mathbf{1}_{(i_j<0)} \cdot S \cdot |i_j| + \mathbf{1}_{(i_j \notin [-ak, ak])} \cdot \xi_j \cdot w_t$$

$$\xi_j \sim U[0, \bar{\xi}]$$

- How large should the adjustment costs be, respectively?

Parameter	Description	Value
Adjustment Costs		
$\bar{\xi}$	Upper bound of fixed cost	
S	Partial Irreversibility	
ϕ_k	Quadratic adjustment cost	

Targets

- Cross-section Moments of Investment: *(Zwick and Mohan 2017)*

Moment	Description (annual)	Data	Model
$\mathbf{E}[i/k]$	Mean investment rate	10.4%	
$\sigma(i/k)$	Standard dev. of investment rates	0.16	
$P(i/k \geqslant 20\%)$	Spike rate of investment	14.4%	
$P(i/k < 20\%)$	Positive rate of investment	85.6%	

- Dynamic Moments of Investment: *(Zwick and Mohan 2017, Baley and Blanco 2020)*

Moment	Description (annual)	Data	Model
$Cor(\frac{i}{k}, \frac{i_{+1}}{k_{+1}})$	Autocorrelation of investment rates	0.40	
$Cov(x, age)$	Covariance of capital gap and age since last adj.	0.29	

*capital gap: $x = log(\frac{k_t}{z_t}) - E\left[log(\frac{k_t}{z_t})\right]$, without frictions, capital gap$= 0$.

- I pin down these parameters using both cross-section and dynamic moments

1.The choice of ϕ_k

- The Choice of ϕ_k: (the conventional cost in the literature)

  I choose quad. adj. costs to match the cross-section moments $\Rightarrow$ $\phi_k = 4.00$

- Cross-section Moments of Investment: *(Zwick and Mohan 2017)*

Moment	**Description**	Data	Model
$\mathbf{E}\,[i/k]$	Mean investment rate (annual)	10.4%	10.1%
$\sigma(i/k)$	Standard dev. of investment rates (annual)	0.16	0.12
$P\,(i/k \geqslant 20\%)$	Spike rate of investment (annual)	14.4%	15.3%
$P\,(i/k < 20\%)$	Positive rate of investment (annual)	85.6%	84.7%

- Next, I pin down the lumpy adj. parameters using both dynamic moments

- Dynamic Moments of Investment: *(Zwick and Mohan 2017, Baley and Blanco 2020)*

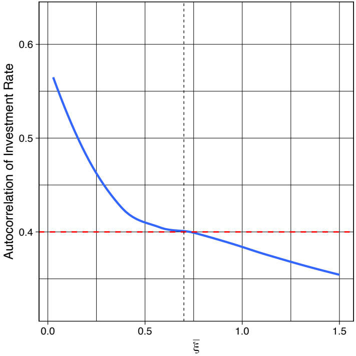
Moment	**Description (annual)**	Data	Model
$Cor(\frac{i}{k}, \frac{i_{+1}}{k_{+1}})$	Autocorrelation of investment rates	0.40	
$Cov(x, age)$	Covariance of capital gap and age since last adj.	0.29	

*capital gap: $x = log(\frac{k_t}{z_t}) - E\left[log(\frac{k_t}{z_t})\right]$, without frictions, capital gap$= 0$.

1.The choice of $\bar{\xi}$

- First, the autocorrelation of investment rates almost uniquely pins down the upper bound of random fixed costs $\bar{\xi} = 0.70$

Figure: Autocorrelation of Investment Rates

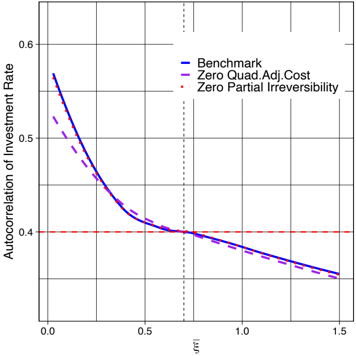


- The reason is that this cost is the only "random" cost, which will decrease the autocorrelation monotonically with the existence of other costs

1.The choice of $\bar{\xi}$

- First, the autocorrelation of investment rates almost uniquely pins down the upper bound of random fixed costs $\bar{\xi} = 0.70$

Figure: Autocorrelation of Investment Rates

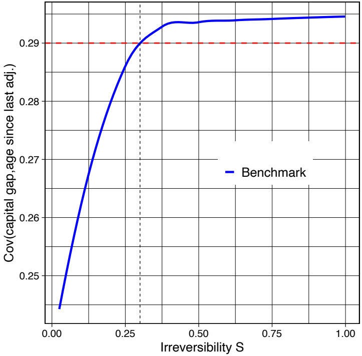


- The reason is that this cost is the only "random" cost, which will decrease the autocorrelation monotonically with the existence of other costs

2.The choice of S

- Second, conditional on $\bar{\xi} = 0.7$, the covariance of capital gap and no-adjustment age since last adjustment suggests a large partial irreversibility $S = 0.3$

Figure: Covariance of capital gap and no-adjustment age since last adjustment



- The reason is that larger irreversibility constraints firms to disinvest so positive capital gap $x = log(\frac{k_t}{z_t}) - E\left[log(\frac{k_t}{z_t})\right] > 0$ lasts longer *age* (natural depreciation)

How does the choice of $\bar{\xi}$ and S matter for the story?

- $\bar{\xi}$ governs how sensitive lumpy investment is w.r.t monetary policy shocks
- S governs how sensitive lumpy investment is w.r.t volatility shocks
- Only empirically consistent $\bar{\xi}$ & S could generate data consistent IRFs to monetary policy shocks and volatility shocks, and eventually volatility-dependent IRFs to monetary policy

Fly to sensitivity

Parameters to be computed

- How large should the adjustment costs be, respectively?

Parameter	Description	Value
Adjustment Costs		
$\bar{\xi}$	Upper bound of fixed cost	0.70
S	Partial Irreversibility	0.30
ϕ_k	Quadratic adjustment cost	4.00

Targets

- Cross-section Moments of Investment: *(Zwick and Mohan 2017)*

Moment	Description	Data	Model
$\mathbf{E}\,[i/k]$	Mean investment rate (annual)	10.4%	10.1%
$\sigma(i/k)$	Standard dev. of investment rates (annual)	0.16	0.12
$P\,(i/k \geqslant 20\%)$	Spike rate of investment (annual)	14.4%	15.3%
$P\,(i/k < 20\%)$	Positive rate of investment (annual)	85.6%	84.7%

- Dynamic Moments of Investment: *(Zwick and Mohan 2017, Baley and Blanco 2020)*

Moment	Description (annual)	Data	Model
$Cor(\frac{i}{k}, \frac{i_{+1}}{k_{+1}})$	Autocorrelation of investment rates	0.40	0.40
$Cov(x, age)$	Covariance of capital gap and age since last adj.	0.29	0.29

*capital gap: $x = log(\frac{k_t}{z_t}) - E\left[log(\frac{k_t}{z_t})\right]$, without frictions, capital gap$= 0$.

- The dynamic moments are essential so that investment is of empirically consistent sensitivity to monetary shocks and volatility shocks

Roadmap of the Quantitative Theory

1. A heterogeneous firm New Keynesian model with lumpy investment
2. Volatility shock and the solution method
3. Parameterization and identification of lumpy investment
4. **Volatility-dependent effectiveness of monetary policy**
5. Inspecting the mechanism in the model

The volatility-dependent effectiveness of monetary policy

Two experiments:

- Low Vol.: a conventional MP shock to TR residual $\epsilon_1^m = -25bps$ with $\rho^m = 0.5$
- High Vol.: the same MP shock when a volatility shock hits as well

A Fair Comparison:

- Impulse Responses of Low Volatility vs. High Volatility w.r.t the MP shock
- Compute the peak responses in both cases when the MP shock hits

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}\downarrow$	$IQR_{sg}\uparrow$
Data	2.0%	0.18	0.75%	0.26	62%	44%
Model		0.18		0.26		44%

- The model explains ???% of the reduction in the effectiveness of monetary policy

The volatility-dependent effectiveness of monetary policy

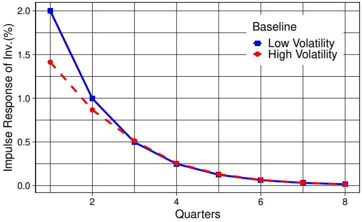
	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data	2.0%	0.18	0.75%	0.26	62%	44%
Model		0.18		0.26		44%

The volatility-dependent effectiveness of monetary policy

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data	2.0%	0.18	0.75%	0.26	62%	44%
Model		0.18		0.26		44%

- Monetary policy generates less IRFs of investment when volatility is high

Figure: Differential IRFs w.r.t. a monetary shock



IRFs of Other Variables | IRFs to Volatility | Decision Rules | Heat-map Plot

The volatility-dependent effectiveness of monetary policy

- Compare the peak impulse response in both cases when the MP shock hits

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m} \downarrow$	$IQR_{sg} \uparrow$
Data	2.0%	0.18	0.75%	0.26	62%	44%
Model	2.0%	0.18	1.4%	0.26	30%	44%

The volatility-dependent effectiveness of monetary policy

- Compare the peak impulse response in both cases when the MP shock hits

	Low Volatility		High Volatility		Δ Effectiveness	
Sources	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}$	IQR_{sg}	$\frac{dI}{d\epsilon^m}\downarrow$	$IQR_{sg}\uparrow$
Data	2.0%	0.18	0.75%	0.26	62%	44%
Model	2.0%	0.18	1.4%	0.26	30%	44%

- The model explains $\frac{30}{62} = 48\%$ of the reduction in the effectiveness of MP

- The result is within the confidence interval of my estimates.

Corresponding Moments

The volatility-dependent effectiveness of monetary policy

- The model successfully replicates the reduction in the effectiveness of MP
- The result is within the confidence interval of my estimates.
- Specification of lumpy investment parameters is the key.

Let's fly to the conclusion if we do not have enough time Conclusion

Roadmap of the Quantitative Theory

1. A heterogeneous firm New Keynesian model with lumpy investment
2. Volatility shock and the solution method
3. Parameterization and identification of lumpy investment
4. Volatility-dependent effectiveness of monetary policy
5. **Inspecting the mechanism in the model**

Key mechanism in the model

- Monetary policy is less effective stimulating aggregate investment:

$$\underbrace{\frac{dI}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} = \underbrace{\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\downarrow\downarrow} + \underbrace{\frac{d\sum_{j\in IM} i_j}{d\epsilon_t^m}(\sigma_t)}_{\approx}, \text{ when } \sigma_t \uparrow$$

- **1 Extensive margin is less responsive to MP with elevated volatility**

$$\frac{d\sum_{j\in EM} i_j}{d\epsilon_t^m}(\sigma_t) \downarrow, \text{ when } \sigma_t \uparrow$$

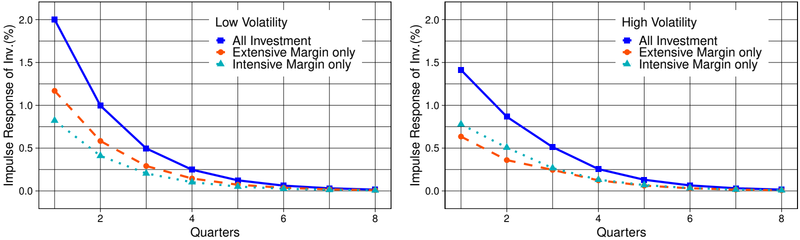
- **2 Reasonable sensitivity of investment to interest rate and volatility**

$$\text{Both data consistent } \frac{d\sum_{j\in EM} i_j}{dr} \quad \& \quad \frac{d\sum_{j\in EM} i_j}{d\sigma}$$

Key mechanism in the model: Inspection 1

- The decrease of the extensive margin accounts for most of the drops (90%)

	Low Volatility			High Volatility		
IRFs	Total	EM	IM	Total	EM	IM
Number	2.0%	1.17%	0.82%	1.4%	0.63%	0.78%



(a) Low Volatility (b) High Volatility

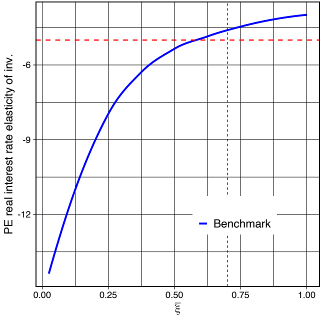
IRFs of Other Variables | IRFs to Volatility | Decision Rules | Heat-map Plot

Key mechanism in the model: Inspection 2

- Elasticity of investment to real interest rate should be -5 (Koby-Wolf-2020)
- Elasticity of investment to volatility should be negatively large (Bloom-2009)
- My choices of $\bar{\xi}$ and S match both sensitivities in considerable ranges

Key mechanism in the model: Inspection 2

- Elasticity of investment to real interest rate should be -5 (Koby-Wolf-2020)
- Elasticity of investment to volatility should be negatively large (Bloom-2009)
- My choices of $\bar{\xi}$ and S match both sensitivities in considerable ranges



(a) Sensitivity to real interest

Key mechanism in the model: Inspection 2

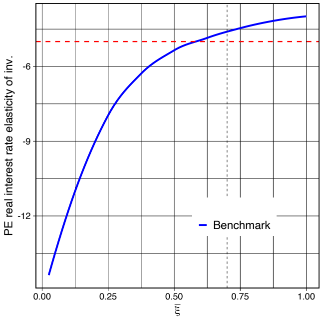
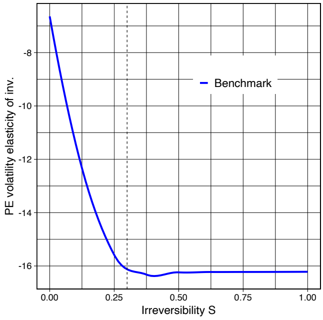
- My choices of $\bar{\xi}$ and S match both sensitivities in considerable ranges



(a) Sensitivity to real interest



(b) Sensitivity to volatility

Back to Identification
Plots with variations in other parameters

Summary of the mechanism

Lumpy investment and volatility play essential roles:

1. The inv. channel of monetary policy works mainly through the extensive margin
2. Extensive margin adjustment probability is lowered when volatility is elevated
3. The decrease of the extensive margin accounts for most of the drops (90%).

Which one of the lumpy capital adjustment costs plays the central role? Both

4. Random fixed costs govern the sensitivity of investment to interest rate
5. Irreversibility governs the sensitivity of investment to volatility
6. Jointly, they determine the volatility-dependent effectiveness of monetary policy

Extensions (ongoing or done, not in the paper)

- Do R&D investments fit the extensive-margin patterns? ✓
- Do organization investments fit the extensive-margin patterns? ✓
- Do external financial frictions generate similar extensive-margin patterns? ✓
- Does firm entry/exit generate similar extensive-margin patterns? ✓in the model
- Could aggregate (linear) fiscal policy resolve the effectiveness issue? $\times$
- Could distributional (non-linear) fiscal policy resolve the effectiveness issue? ✓

Conclusion

- I estimated the volatility-dependent effectiveness of monetary policy in the data.
- I show that this estimate is consistent with the implications of a macro investment model with a plausible parameterization of firm-level adjustment costs.
- This implies that fluctuations in volatility interacting with lumpy investment play an essential role in monetary policy transmission to aggregate investment
- Further work: Refine the extensions above

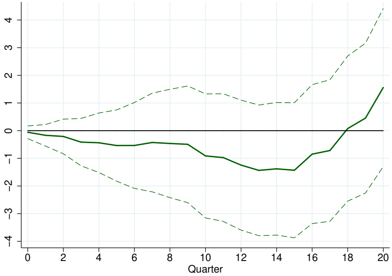
Results of Interacted Regression

back

Interacted Local Projection Specification following Jorda (2005)

$$\Delta_h I_{t+h} = \alpha_h + (\beta_h + \gamma_h \sigma_t) \times \epsilon_t^m + \sum_{l=0}^{L} \Gamma'_{h,t-l} Z_{t-l} + \epsilon_{h,t}$$

Figure: Differential Investment Responses to Monetary Shocks



Firm-level Regressions ▸ back

- Data: Aggregate variables are same; Firm-level variables are from Compustat.
- Probit Local Projection at Extensive Margin:

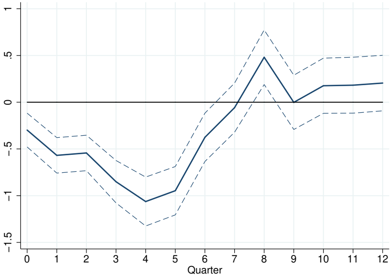
$$A^*_{j,t+h} = (\beta_h + \boldsymbol{\gamma_h}\sigma_t) \times \epsilon^m_t + \sum_{l=0}^{L} \Gamma'_{h,t-l} X_{j,t-l} + \sum_{l=0}^{L} \Gamma'_{h,t-l} Z_{t-l} + \epsilon_{j,h,t} \tag{7}$$

$$A_{j,t+h} = \begin{cases} 1, & \text{if } A^*_{j,t+h} > 1\% \\ 0, & \text{otherwise} \end{cases} \tag{8}$$

- The estimated coefficients of a Probit model is harder to interpret. Suppose we fix all other regressors at $X^*_{j,t}\beta_h$, the probability of a firm making active investment is $P(A_{j,h} = 1|X^*_{j,t}) = \Phi\left(X^*_{j,t}\beta_h + (\beta_h + \boldsymbol{\gamma_h}\sigma_t) \times \epsilon^m_t\right)$.

Firm-level Regressions: Extensive Margin ▸ back

Figure: Firm-level Differential Response to Monetary Shocks (Extensive Margin)



- For an average firm (demeaned, so $X^*_{j,t} = 0$), the effects of a conventional expansion will generate roughly 3% adjustment probability drop $[\Phi(0) - \Phi(-0.08)]$ bottomed at quarter 4 if volatility increases from 0.18 to 0.26. (Cautious: please do not take it seriously until further verification.)

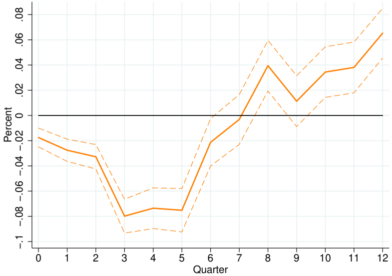
Firm-level Regressions: Intensive Margin ▸ back

Tobit Local Projection at Intensive Margin:

$$\Delta_h I_{j,t+h} = \left\{ \begin{array}{l} \Delta_h^* I_{j,t+h} = (\beta_h + \boldsymbol{\gamma_h} \sigma_t) \times \epsilon_t^m + \sum_{l=0}^{L} \Gamma'_{h,t-l} X_{j,t-l} \\ \qquad\qquad + \sum_{l=0}^{L} \Gamma'_{h,t-l} Z_{t-l} + \epsilon_{j,h,t}, \text{ if } \Delta_h^* I_{j,t+h} > 1\% \\ \quad 0, \text{ otherwise} \end{array} \right\}.$$

Firm-level Regressions: Intensive Margin ▸ back

Figure: Firm-level Differential Response to Monetary Shocks (Intensive Margin)



- The effects of a conventional expansion will generate roughly 0.64% [$\{\gamma_3 = 0.08\}$ $\times$ $\{\Delta_{IQR} = 0.08\}$] lower investment rate at quarter 3 if volatility increases by 0.08. (Cautious: please do not take it seriously until further verification.)

Recursive Production Firms' Problem

Back

- Value Function

$$V^A(k_{jt}, z_{jt}; \Omega_t) = \max_{i,n} \left\{ -c(i_{jt}) + \mathbb{E}[p_t^w y_{jt} - w_t n_{jt} + \Lambda_{t,t+1} V(k^*_{jt+1}, z_{jt+1}; \Omega_{t+1}] \right\}$$

$$V^{NA}(k_{jt}, z_{jt}; \Omega_t) = \max_{i \in [-ak, ak], n} \left\{ -c(i_{jt}) + \mathbb{E}[p_t^w y_{jt} - w_t n_{jt} + \Lambda_{t,t+1} V((k^C_{jt+1}, z_{jt+1}; \Omega_{t+1}] \right\}$$

$$\begin{aligned} V(k_{jt}, z_{jt}; \Omega_t) = & -\frac{w_t \xi^*(k_{jt}, z_{jt}; \Omega_t)}{2} + \frac{\xi^*(k_{jt}, z_{jt}; \Omega_t)}{\bar{\xi}} V^A(k_{jt}, z_{jt}; \Omega_t) \\ & + \left(1 - \frac{\xi^*(k_{jt}, z_{jt}; \Omega_t)}{\bar{\xi}}\right) V^{NA}(k_{jt}, z_{jt}; \Omega_t) \end{aligned} \tag{9}$$

- Optimal Investment Decisions

$$\xi_t^*(k_{jt}, z_{jt}; \Omega_t) = \frac{V^A(k_{jt}, z_{jt}; \Omega_t) - V^{NA}(k_{jt}, z_{jt}; \Omega_t)}{w_t} \tag{10}$$

$$k_{jt+1} = \begin{cases} (1-\delta)k_{jt} + i^*_{jt} & \xi_{jt} < \xi^*(k_{jt}, z_{jt}; \Omega_t) \\ (1-\delta)k_{jt} + i^C_{jt} & otherwise \end{cases} \tag{11}$$

Production firms ▸ back

Enter period with state variables (z_{jt}, k_{jt})

1. Idiosyncratic TFP shock:

$$log(z_{jt}) = -\frac{{\sigma_z}^2}{2(1+\rho)} + \rho_z log(z_{jt-1}) + \sigma_z \epsilon_{jt} \tag{12}$$

2. Volatility shock: (timing)
   - t^-: A heightened change in the standard deviation of TFP innovation ($\sigma_z \uparrow$)
   - t : Firms making investment decisions under uncertainty
   - t^+: Productivity z_{jt} arrives and firms making production decisions

Details of the simulation

- I simulate 100k firms starting from a steady-state for 500 quarters
- Both volatility shock and monetary shock hit at the quarter 501
- The economy convergences back to steady-state in the quarter 700
- Largest firms who account for 45% of output are "Compustat" firms ($\sim$ 10%)
- "Compustat firms" older than 100+ quarters are used to calculate IQR_{sg} ($\sim$ 1%)
- Additional IQRs: (I choose $\sigma^l = 0.05$ and $\sigma^h = 0.13$ to match IQR_{sg} in the data)

	Low Volatility		High Volatility	
Sources	σ_z^l	IQR_{sg}	σ_z^h	IQR_{sg}
